May 10, 2023

1 INTRODUCTION

Rust-eze is modern, object-oriented, type-safe programming language. It inherits the best parts of Rust and Java to provide a fast and memory-safe language for the object-oriented paradigm, while also bringing in some influence from Pascal. Rust-eze does, however, differ from its parent languages in the following ways:

1. Rust-eze is an object-oriented language, which means there are no structs and only classes/objects and enums.
2. Like Java, but unlike Rust, Rust-eze is statically typed, so all variables must be explicitly defined with their respective types.
3. Similar to Rust, but unlike Java, Rust-eze uses a system of borrowing and ownership so only one variable can point to a given place in memory at a time. This prevents the need for a garbage collector as variables are automatically dropped and the memory is freed when they go out of scope.
4. Unlike Java, but like Rust, Rust-eze is compiled into the native binary, so there is no need for a JVM or an intermediate bytecode representation of Rust-eze programs.
5. Similar to Rust, all instance variables must be initialized within the constructor.
6. Similar to both parent languages, all classes belong to a module (Java package). However, more similar to Rust, the module is inferred based on the relative file location and does not have to be explicitly defined within the file.

1.1 GENEALOGY

1.2 HELLO WORLD

```
1 model HelloWorld
2 start
3     ext fn main(Vec<String> args) -> void
4         start
5             println("Hello_world!");
6         finish main
7 finish model
```

Listing 1: HelloWorld.rez

1.3 PROGRAM STRUCTURE

The key organizational concepts in Rust-eze are as follows:

1. Every file contains a single **model** (equivalent to a class), which should be the same name as the file minus the .rez file extension.
2. All instance members default to being in the interior unless they are declared with the **ext** keyword to note their exterior presence.
3. Instance variables are declared within the **specs** block and must be initialized within the constructor, which is a function that is the same name as the model.
4. Local variables are immutable by default unless they are declared with the **mut** keyword.
5. The entry point for all Rust-eze programs is the main method that is located in one of the models of the project.

The program below defines a new **model** called **Lightning** that contains 3 instance variables: a **String** that is public called *name*, a public integer called *age*, and a private integer called *miles*. Each of these instance variables are initialized within the constructor. Each **Lightning** has 2 member functions: *drive* and *say_it*. *drive* is an exterior method as it is defined with the **ext** keyword. Since it modifies an instance variable, it must take it a mutable reference to the object in addition to the number of miles being driven. Inside of the method, a new local variable called *new_mileage* is declared without the **mut** keyword, meaning that it is immutable and is a constant with the value it is initialized with. The other instance method, *say_it*, is also public and does not modify the instance variables, which is why it needs an immutable reference to **self**.

```
1 model Lightning
2 start
3     specs
4         start
5             ext String name;
6             ext i32 age;
7             i32 miles;
8         finish specs
9
10    ext fn Lightning(String my_name, i32 my_age)
11        start
12            self.name := my_name;
13            self.age := my_age;
14            self.miles := 0;
15        finish Lightning
16
17    ext fn drive(&mut self, i32 num_miles) -> void
18        start
19            i32 new_mileage := self.miles + num_miles;
20            self.miles := new_mileage;
21        finish drive
```

```

22
23     ext fn say_it(&self) -> void
24     start
25         println("Kachow!");
26     finish say_it
27 finish model

```

Listing 2: Lightning.rez

Next, the Lightning model is imported to a new file called *Main.rez* and is initialized within the main method. Since the **mut** keyword is used, we can use the mutable method of *drive* on the new object as well as directly modify its public instance variables. After *the_lightning*'s name is printed, we call its *say_it* method and then call the *drive* method with an input of 42 miles to increase the object's mileage.

```

1 import garage.Lightning;
2
3 model Main
4 start
5     ext fn main(Vec<String> args) -> void
6     start
7         mut Lightning the_lightning := new Lightning("McQueen", 17);
8         println(the_lightning.name);
9
10         the_lightning.say_it();
11         the_lightning.drive(42);
12     finish main
13 finish model

```

Listing 3: Main.rez

1.4 TYPES AND VARIABLES

There are two kinds of variables in Rust-eze: *value types* and *reference types*. Variables of value types directly contain their data, while variables of reference types store references to their data or objects in memory. Due to the ownership system, only one variable of a reference type can point to a particular place in memory at a given time. See Section 3 for details.

1.5 VISIBILITY

In Rust-eze, visibility of methods and instance variables is defined as either interior (private) or exterior (public). Everything is part of the interior unless explicitly stated to be in the exterior. Once a variable or method is public, it may be accessed outside of the model in which it is defined.

1.6 STATEMENTS DIFFERING FROM RUST AND JAVA

| Statement | Example |
|----------------------|---|
| Assignment statement | <pre> mut i32 x := 5; x = 3; i32 y := x + 2; </pre> |

| | |
|--------------|--|
| If statement | <pre> i32 x := 7; if x > 3 && x < 9 start println("Hello_there") else println("Kachow") finish if </pre> |
| For loop | <pre> for mut i32 i in range(0, 10, 1) start println(i) finish for </pre> |
| While loop | <pre> mut i32 i := 0; while i < 10 start println(i); i := i + 1; finish while </pre> |

2 LEXICAL STRUCTURE

2.1 PROGRAMS

A Rust-eze program consists of one or more source files. A source file is an ordered sequence of (probably) Unicode characters.

Conceptually speaking, a program is compiled using five steps:

1. Transformation, which converts a file from a particular character repertoire and encoding scheme into a sequence of Unicode characters.
2. Lexical analysis, which translates a stream of Unicode input characters into a stream of tokens.
3. Syntactic analysis (parsing), which translates the stream of tokens into a concrete syntax tree (CST).
4. Semantic analysis, which converts the CST into an abstract syntax tree (AST) and is passed to the semantic analyzer for type checking and the borrow checker to make sure all variables referenced are active owners of data.
5. Code generation, which converts the AST into executable code for the target platform and CPU architecture.

2.2 GRAMMARS

This specification presents the syntax of the Rust-eze programming language where it differs from Rust and Java.

```

<assignment operator> → :=
<block begin> → start
<block end> → finish
<print> → println
<visibility modifier> → ext | ε
<mutability modifier> → mut | ε

```

$\langle \text{model definition} \rangle \rightarrow \text{model } \langle \text{model name} \rangle \langle \text{parent declaration} \rangle \langle \text{block begin} \rangle \langle \text{statements} \rangle$
 $\langle \text{block end} \rangle \text{ model}$
 $\langle \text{parent declaration} \rangle \rightarrow \text{extends } \langle \text{parent model name} \rangle \mid \epsilon$
 $\langle \text{specs definition} \rangle \rightarrow \text{specs } \langle \text{block begin} \rangle \langle \text{spec definition} \rangle \langle \text{block end} \rangle \text{ specs}$
 $\langle \text{spec definition} \rangle \rightarrow \langle \text{visibility modifier} \rangle \langle \text{type} \rangle \langle \text{spec name} \rangle ; \langle \text{spec definition} \rangle \mid \epsilon$
 $\langle \text{variable declaration} \rangle \rightarrow \langle \text{mutability modifier} \rangle \langle \text{type} \rangle \langle \text{variable name} \rangle \langle \text{assignment operator} \rangle$
 $\langle \text{expression} \rangle ;$
 $\langle \text{if statement} \rangle \rightarrow \text{if } \langle \text{condition} \rangle \langle \text{block begin} \rangle \langle \text{statements} \rangle \text{ else } \langle \text{statements} \rangle \langle \text{block end} \rangle \text{ if}$
 $\langle \text{for loop} \rangle \rightarrow \text{for mut } \langle \text{type} \rangle \langle \text{var name} \rangle \text{ in } \langle \text{expr} \rangle \langle \text{block begin} \rangle \langle \text{statements} \rangle \langle \text{block end} \rangle \text{ for}$
 $\langle \text{while loop} \rangle \rightarrow \text{while } \langle \text{condition} \rangle \langle \text{block begin} \rangle \langle \text{statements} \rangle \langle \text{block end} \rangle \text{ while}$
 $\langle \text{function definition} \rangle \rightarrow \langle \text{visibility modifier} \rangle \text{ fn } \langle \text{function name} \rangle (\langle \text{parameter list} \rangle) \text{ -} \rangle \langle \text{return type} \rangle$
 $\langle \text{block begin} \rangle \langle \text{statements} \rangle \langle \text{block end} \rangle \langle \text{function name} \rangle$
 $\langle \text{parameter list} \rangle \rightarrow \langle \text{type} \rangle \langle \text{parameter name} \rangle , \langle \text{parameter list} \rangle \mid \epsilon$

2.3.1 COMMENTS

2.4 TOKENS

Tokens:

- identifier
- keyword
- integer literal
- real literal
- character literal
- string literal
- operator or punctuation

2.4.1 KEYWORDS DIFFERENT FROM RUST AND JAVA

New keywords: range, model, specs, start, finish, ext

Removed keywords: use, class, match, do, private, byte, short, str, boolean, static, public, double, long, float, int, as, pub, impl, struct

3 TYPE SYSTEM

Rust-eze uses a strong static type system. This means that the Rust-eze compiler will catch type mismatch errors at compile time through early binding compile-time type checking.

3.1 TYPE RULES

The type rules for Rust-eze are as follows:

$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a primitive type} \end{array}$$

$$S \vdash e1 := e2 : T$$
$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a primitive type} \end{array}$$

$$S \vdash e1 == e2 : \text{bool}$$
$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a primitive type} \end{array}$$

$$S \vdash e1 != e2 : \text{bool}$$
$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a numeric primitive type} \end{array}$$

$$S \vdash e1 > e2 : \text{bool}$$
$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a numeric primitive type} \end{array}$$

$$S \vdash e1 < e2 : \text{bool}$$
$$\begin{array}{l} S \vdash e1 : T \\ S \vdash e2 : T \\ T \text{ is a numeric primitive type} \end{array}$$

$$S \vdash e1 + e2 : T$$

$S \vdash e1 : \text{String}$
 $S \vdash e2 : \text{String}$

 $S \vdash e1 + e2 : \text{String}$

3.2 VALUE TYPES

| Data Type | Description |
|-------------------|---|
| i8, i16, i32, i64 | Signed integers that store up to X bits, where X is the number after "i" in the data type. |
| u8, u16, u32, u64 | Unsigned integers that store up to X bits, where X is the number after "u" in the data type. |
| f32, f64 | Floating point numbers that store up to X bits, where X is the number after "f" in the data type. |
| bool | Boolean value that can be either false or true . |
| char | Character value that stores the data for a single character. |

3.3 REFERENCE TYPES

| Data Type | Description |
|-----------|--|
| String | A sequence of characters Example: <pre>String x := "hello";</pre> |
| Vec<T> | A dynamic, homogeneous array of values of type T, which can be any type. Example: <pre>mut Vec<i32> nums := new Vec<i32>(3); nums[0] := 0; nums[1] := 0; nums[2] := 7;</pre> |
| Tuple | A collection of values of different types that is fixed in size. Example: <pre>Tuple<i32, bool, i32> my_tuple := (7, false, 3);</pre> |

4 EXAMPLE PROGRAMS

4.1 CAESAR CIPHER ENCRYPT

```

1 // Model definition for the Caesar cipher
2 model CaesarCipher
3 start
4     // Encrypt a string based on the shift amount
5     ext fn encrypt(&self, &String in_str, i32 shift_amt) -> String
6     start
7         // Get the real shift amount and create a new vector of characters
8         i32 real_shift := shift_amt % 26;
9         Vec<char> out_vec := new Vec<char>();
10
11        // Loop through the entire string
12        for mut i32 i in range(0, in_str.len(), 1)
13        start
14
15            // Get the character at the given index as an integer
16            // (i8) casts the expression on the right of it to be an i8
17            mut i8 cur_char := (i8) in_str.char_at(i);
18
19            if cur_char >= 97 && cur_char <= 122
20            start
21                // Convert the lowercase letters to uppercase letters
22                cur_char := cur_char - 32;
23            finish if
24
25            // Only modify uppercase letters
26            if cur_char >= 65 && cur_char <= 90
27            start
28                // Perform the shift
29                cur_char := cur_char + real_shift;
30
31                // This is the difference for wraparound for Z
32                mut i32 diff := cur_char - 90;
33                if diff > 0
34                start
35                    // Perform the Z wraparound
36                    cur_char := 65 + diff - 1;
37                else
38                    // Now compute the A wraparound if there was no Z wraparound
39                    diff := 65 - cur_char;
40
41                    if diff > 0
42                    start
43                        cur_char := 90 - diff + 1;
44                    finish if
45                finish if
46            finish if
47
48            // Get the final character as the appropriate type
49            char final_char := (char) cur_char;
50
51            // Push it to the end of the vector (vector will resize as needed)
52            out_vec.push(final_char);
53        finish for
54
55        // Join the elements of the vector together to form a string
56        // by using the string representation of each of the elements
57        return out_vec.join("");
58    finish encrypt
59
60    ext fn main(Vec<String> args) -> void
61    start
62        CaesarCipher cipher := new CaesarCipher();
63
64        // Create a new string

```

```

65     String x := "Kachow";
66
67     // Perform encrypt and pass an immutable reference to x
68     String y := cipher.encrypt(&x, 95);
69
70     // Should print Kachow
71     println(x);
72     // Should print BRTYFN
73     println(y);
74 finish main
75 finish model

```

Listing 4: CaesarCipher.rez

4.2 CAESAR CIPHER DECRYPT

```

1 model CaesarCipher
2 start
3     // Returns a decrypted string based on the shift amount
4     ext fn decrypt(&self, &String in_str, i32 shift_amt) -> String
5     start
6         // Decrypt is the same as encrypt with negative shift amount
7         // Encrypt is defined in Section 4.1
8         return self.encrypt(in_str, -shift_amt);
9     finish encrypt
10
11     ext fn main(Vec<String> args) -> void
12     start
13         CaesarCipher cipher := new CaesarCipher();
14
15         String x := "Kachow";
16         String y := cipher.encrypt(&x, 95);
17         String z := cipher.decrypt(&y, 95);
18         // Kachow
19         println(x);
20         // BRTYFN
21         println(y);
22         // KACHOW
23         println(z);
24     finish main
25 finish model

```

Listing 5: CaesarCipher.rez (enhanced)

4.3 FACTORIAL

```

1 // Define a model for the factorial program
2 model FactorialProgram
3 start
4     // Return the result of factorial(num)
5     ext fn factorial(&self, i32 num) -> i32
6     start
7         if num <= 0
8         start
9             // factorial(0) = 1
10            // and anything < 0 is invalid, so return 1
11            return 1;
12        else
13            // factorial(n) = n * factorial(n - 1)
14            return num * self.factorial(num - 1);
15        finish if

```

```

16     finish factorial
17
18     ext fn main(Vec<String> args) -> void
19     start
20         FactorialProgram fp := new FactorialProgram();
21         // Should be 120
22         println(fp.factorial(5));
23
24         // Both should be 1
25         println(fp.factorial(0));
26         println(fp.factorial(-1));
27     finish main
28 finish model

```

Listing 6: FatorialProgram.rez

4.4 QUICKSORT

```

1 // Import the Random model for use later
2 import std.util.Random;
3
4 // Define a model for the classic SortsAndShuffles file from algorithms
5 model SortsAndShuffles
6 start
7     // This is the wrapper function for the quicksort implementation
8     ext fn quicksort(&self, &mut Vec<i32> data) -> void
9     start
10         // Call quicksort on the entire vector
11         self.quicksort_with_indices(data, 0, data.len() - 1);
12     finish quicksort
13
14     // Helper quicksort function
15     // Private because only accessible within the model
16     fn quicksort_with_indices(&self, &mut Vec<i32> data, i32 start_index, i32 end_index) ->
17         void
18     start
19         // Recursion base case to end if we have an array of size 0 or 1
20         if start_index >= end_index
21         start
22             return;
23         finish if
24
25         // Declare a pivot index that will be changed in a few lines
26         mut i32 pivot_index := 0;
27
28         if end_index - start_index < 3
29         start
30             // Pivot index is the start index because will need one more level
31             // of recursion regardless of the pivot
32             pivot_index := start_index;
33         else
34             // Otherwise declare a new random object
35             Random ran := new Random();
36
37             // Get the first pivot option
38             i32 pivot_choice_1 := ran.randInt(start_index, end_index + 1);
39
40             // Get the second pivot option, but only use it if different from
41             // the first
42             mut i32 pivot_choice_2 := ran.randInt(start_index, end_index + 1);
43             while pivot_choice_2 == pivot_choice_1
44                 start
45                     pivot_choice_2 := ran.randInt(start_index, end_index + 1);

```

```

45     finish while
46
47     // Get the third pivot option but only use it if different from
48     // both of the other options
49     mut pivot_choice_3 := ran.randint(start_index, end_index + 1);
